

One-Take Shooting Script

ListingOS · OpenAI Build Week · single continuous take, 3 angles + screen recording, live publish
Target 2:45–2:55 · ~420 spoken words · live narration, your own voice

Pick your item first

This one decision changes your risk more than anything else on the day. Both paths are legitimate; they fail differently.

	SAFE PATH — unbranded item	STRONGER PATH — graded card
Use	Leather wallet or sunglasses	Warturtle PSA 10 (3 exact comps, scored 0.87 ready)
Why	BrandMPN auto-repair covers you. Fires only for US marketplace, non-card, unbranded evidence — all true here.	The refusal beat is the most impressive thing the product does. Better story if it holds.
Risk	Low. Cleanest publish. Slightly less memorable.	Pricing locks if fewer than 2 exact comps are live at that moment. Comp data shifts hour to hour.
If it fails	Cut to the pre-published listing tab.	Set a manual price — that clears the publish gate — then continue. Rehearse where that field is.

Settle it before you light anything. Run your chosen item through the app right now. Comes back **ready** with a real price → shoot it. Comes back **needs_input** → switch to the wallet. Five minutes, removes all doubt.

Pre-flight

Everything here happens before anyone rolls.

Device

- [] Do Not Disturb **on** — no notification banners mid-take
- [] eBay account connected; confirm the seller state on Home **before** rolling
- [] Four photos already in the gallery **and indexed by the picker** (ADB-pushed images need a MediaStore scan first)
- [] App opened once already, so there is no cold-start delay
- [] Battery above 50%, brightness up, auto-lock off

Capture

- [] Phone screen recording started **before** the cameras roll
- [] All three camera angles framed and rolling
- [] **Clap once, in frame, after the screen recording is already running** — that is your sync point for four separate files

Fallback

- [] A previously published eBay listing open in a browser tab, off camera
- [] You know the expected price, so nothing on screen surprises you
- [] You know where the manual price override field is, in case pricing locks

The final sixty seconds

Three things kill this take. Check them last, in this order:

- 1. Is the screen recording running?** Four media files are useless if the one carrying the UI never started. Confirm it visually, not from memory.
- 2. Is Do Not Disturb on?** A banner across the review screen means a reshoot, because that is the one frame you cannot cut around.
- 3. Have you clapped?** After the screen recording starts, before you speak. No clap, no sync.

Then breathe, and go straight into “I’m Jon.” No warm-up line, no countdown on camera — you will cut the head off anyway.

The Script

Read the bold lines. Italics are direction, not dialogue.

BEAT 1 · Cold open

To camera · ~15s

Straight to camera. No preamble, no greeting, no throat-clearing.

**I'm Jon. I built ListingOS. It turns product photos into a live eBay listing.
The hard part of selling something was never the photo. It's the listing.
Title, category, item specifics, condition, price, policy checks. That's the
part nobody wants to do.
So watch.**

BEAT 2 · Intake

Phone angle + screen · ~30s

Pick up the phone. The screen recording is the hero here; the phone angle is texture.

This is my real eBay account, connected through OAuth.

Open the picker. Select the four photos.

I pick photos of one product.

Hit the strategy control.

And I pick one thing — sell fast, or sell high.

That's the whole input. Photos, and one preference.

Tap create.

**I could put the phone down here and start the next item — it builds in the
background. But let's watch it work.**

BEAT 3 · The wait

Back to camera · ~40s · this is the beat that saves the take

Draft generation ran about 40 seconds in prior tests. Don't stare at a spinner — turn and explain. This is also where Devpost's GPT-5.6 requirement gets satisfied, so the latency becomes your best beat instead of a gap. **If the draft lands early, finish your sentence and move on.** If it runs long, the buffer line at the end is there for you.

While that runs — here's what's actually happening.

The photos go up to Cloudflare R2 and land on a queue. A Cloudflare Worker picks up the job.

It sends the images to GPT-5.6 through the OpenAI Responses API, and asks for strict structured output against a JSON Schema. Not prose — a typed object.

The Worker validates that before anything is persisted. If the model returns something malformed, it never reaches the database.

Then it gets intersected with real eBay evidence — category from the Taxonomy API, item specifics, and active comparable listings from Browse.

So the price isn't the model's opinion. It's evidence.

For graded cards it goes further — PSA cert lookup, catalog resolution, eBay image search. And when identity is weak, it locks the price instead of guessing.

Buffer line — only if it is still processing:

All of it runs on Cloudflare — Workers, D1, R2, KV, and Queues.

BEAT 4 · Review

Screen · ~35s

Scroll slowly and deliberately. One continuous scroll reads better on video than jumping around.

And there it is. One screen.

Title — built out of the words a buyer actually types into eBay search.

Category. Condition. Item specifics. Every field editable. None of it typed by me.

Punch in on the pricing block with the comparables visible.

Price, with the comparables it used. These are active listings — what this thing is being asked for right now.

And a confidence score. Because sometimes the honest answer is “I'm not sure.”

BEAT 5 · Verify and publish

Screen · ~25s

Before it publishes, it verifies against eBay.

If the BrandMPN blocker appears — this is a feature, not a failure. Slow down and let it land:

And there — eBay wants Brand and MPN. This item has neither, so it applies eBay's supported values for exactly that case. I fix it without leaving the page.

Verify. Publish. Let the success state appear before you speak again.

That's a real fixed-price listing. On my own eBay account. Published through eBay's Inventory API.

BEAT 6 · Close

To camera · ~20s

I built this with Codex. The Expo app, the Cloudflare Worker, the eBay OAuth and publish path, the upload queue, the Android debugging.

I made the product calls — what it should do, and what it should refuse to do.

Photos in. Listing out.

The hard part was never the photo. It was the listing. That part's finished.

Hard stop. No fade, no “thanks for watching,” no outro. Hold still for two seconds, then cut.

If It Goes Wrong

One take means something will. Every line below is true, and several make the product look better than a clean run would.

If this happens	Say this	Then
Draft returns needs_input	"And there's the gate. It didn't have enough evidence to be confident, so it's asking me instead of guessing. That's the behavior I want."	Walk the blocker, then publish. This is a strong beat, not a stumble.
Price locked / shows \$0	"No exact comparables — so it won't invent a price. I'd set this one myself."	Enter a manual price. That clears the publish gate. Continue as normal.
Publish rejects on something auto-repair doesn't cover	"eBay's rejecting this one — and that's the point of the verify step. It caught it before the listing went out wrong."	Cut to the pre-published tab. Do not claim the live one succeeded.
Queue runs much longer than expected	"This is real infrastructure, not a canned demo — sometimes it takes a beat."	Use the Cloudflare buffer line, then keep going on architecture.
You fumble a line	<i>Say nothing. Pause. Start the sentence again.</i>	You have three angles — the cut hides it completely. Do not restart the take.

Say-Not-Say

Everything in the script clears your claims ledger. These are the ones easiest to break by improvising.

Say	Never say	Why
"active comparables," "what it's being asked for"	"sold for"	Sold-comps pricing is not implemented.
"fixed-price"	"auction"	No verified auction adapter exists.
"in this run"	"always under a minute"	Latency varies. Demo evidence only.
"it recommends improvements"	"it enhances your photos"	It plans; it does not transform images.
nothing about notifications	"it notifies you on iPhone"	Android delivery was verified; iOS was not.
nothing about test coverage	"fully tested"	No automated E2E suite exists yet.

Nothing on screen that shouldn't be public. No account identifiers, tokens, emails, or .env contents — in any frame, on any monitor behind you, or in any file path if you show code.

After The Take

Immediately

- ☐ Stop the screen recording **last**, after the cameras
- ☐ Confirm the published listing is live and its images are buyer-reachable
- ☐ Decide whether to end the test listing — it is a real one on your account
- ☐ Pull all four files into the edit and sync on the clap

Before upload

- ☐ Watch once, start to finish, purely for anything on screen that shouldn't be public
- ☐ Confirm the audio covers all three: what you built, how GPT-5.6 was used, how Codex was used
- ☐ If you time-compressed the queue wait, say so in the video description
- ☐ Runtime is under 3:00

Submit

- ☐ Upload to YouTube, public or unlisted
- ☐ **Verify playback in an incognito window** — unlisted videos can still be login-gated by mistake
- ☐ Attach the URL to the Devpost project
- ☐ Upload gallery images if not already present
- ☐ **Accept the Official Rules agreement box** — the submission is not complete without it

Deadline

Tuesday 21 July 2026, 5:00 PM Pacific.

The submission form is started but not finalized. The video is the only hard blocker remaining — everything else on the Devpost form is already saved.
